Synonyms

Adding noise; Data perturbation; Recodings; Sampling; Synthetic data

Definition

Matrix Masking refers to a class of statistical disclosure limitation (SDL) methods used to protect confidentiality of statistical data, transforming an $n \times p$ (cases by variables) data matrix Z through pre- and post-multiplication and the possible addition of noise.

Main Text

Duncan and Pearson [3] and many others subsequently categorize the methodology used for SDL in terms of transformations of an $n \times p$ (cases by variables) data matrix Z of the form

$$Z \rightarrow AZB + C, \quad (1)$$

where A is a matrix that operates on the n cases, B is a matrix that operates on the p variables, and C is a matrix that adds perturbations or noise.

Matrix masking includes a wide variety of standard approaches to SDL: (i) adding noise, i.e., the C in matrix masking transformation of equation [1]; (ii) releasing a subset of observations (delete rows from Z), i.e., sampling; (iii) cell suppression for cross-classifications;

(iv) including simulated data (add rows to Z); (v) releasing a subset of variables (delete columns from Z); (vi) switching selected column values for pairs of rows (data swapping). Even when one has applied a mask to a data set, the possibilities of both identity and attribute disclosure remain, although the risks may be substantially diminished.

The entry on *Statistical Disclosure Limitation For Data Access* focuses on four different matrix masking methods (i) sampling; (ii) recodings (e.g., collapsing rows or columns, sometimes referred to as global recoding); (iii) perturbation (including adding noise); and (iv) the use of synthetic data.
