# Subgradients

Ryan Tibshirani Convex Optimization 10-725/36-725

#### Last time: gradient descent

Consider the problem

$$\min_{x} f(x)$$

for f convex and differentiable,  $dom(f) = \mathbb{R}^n$ . Gradient descent: choose initial  $x^{(0)} \in \mathbb{R}^n$ , repeat

$$x^{(k)} = x^{(k-1)} - t_k \cdot \nabla f(x^{(k-1)}), \quad k = 1, 2, 3, \dots$$

Step sizes  $t_k$  chosen to be fixed and small, or by backtracking line search

If  $\nabla f$  Lipschitz, gradient descent has convergence rate  $O(1/\epsilon)$ 

#### Downsides:

- Requires f differentiable  $\leftarrow$  next lecture
- Can be slow to converge ← two lectures from now

#### Outline

Today: crucial mathematical underpinnings!

- Subgradients
- Examples
- Subgradient rules
- Optimality characterizations

#### Subgradients

Remember that for convex and differentiable f,

$$f(y) \ge f(x) + \nabla f(x)^T (y - x)$$
 for all  $x, y$ 

I.e., linear approximation always underestimates f

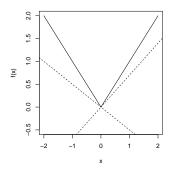

A subgradient of a convex function f at x is any  $g \in \mathbb{R}^n$  such that

$$f(y) \ge f(x) + g^T(y - x)$$
 for all  $y$ 

- Always exists
- If f differentiable at x, then  $g = \nabla f(x)$  uniquely
- Actually, same definition works for nonconvex f (however, subgradients need not exist)

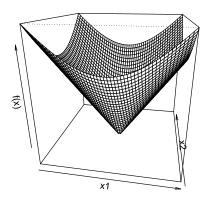

# Examples of subgradients

Consider  $f: \mathbb{R} \to \mathbb{R}$ , f(x) = |x|

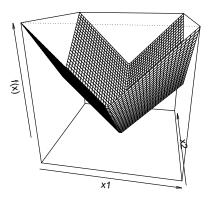

- For  $x \neq 0$ , unique subgradient g = sign(x)
- For x=0, subgradient g is any element of [-1,1]

#### Consider $f: \mathbb{R}^n \to \mathbb{R}$ , $f(x) = ||x||_2$

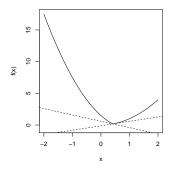

- For  $x \neq 0$ , unique subgradient  $g = x/\|x\|_2$
- For x=0, subgradient g is any element of  $\{z:\|z\|_2\leq 1\}$

#### Consider $f: \mathbb{R}^n \to \mathbb{R}$ , $f(x) = ||x||_1$

- For  $x_i \neq 0$ , unique *i*th component  $g_i = \text{sign}(x_i)$
- For  $x_i=0$ , ith component  $g_i$  is any element of  $\left[-1,1\right]$

Let  $f_1, f_2 : \mathbb{R}^n \to \mathbb{R}$  be convex and differentiable, and consider  $f(x) = \max\{f_1(x), f_2(x)\}$ 

- For  $f_1(x) > f_2(x)$ , unique subgradient  $g = \nabla f_1(x)$
- For  $f_2(x) > f_1(x)$ , unique subgradient  $g = \nabla f_2(x)$
- For  $f_1(x) = f_2(x)$ , subgradient g is any point on the line segment between  $\nabla f_1(x)$  and  $\nabla f_2(x)$

#### Subdifferential

Set of all subgradients of convex f is called the subdifferential:

$$\partial f(x) = \{g \in \mathbb{R}^n : g \text{ is a subgradient of } f \text{ at } x\}$$

- $\partial f(x)$  is closed and convex (even for nonconvex f)
- Nonempty (can be empty for nonconvex f)
- If f is differentiable at x, then  $\partial f(x) = {\nabla f(x)}$
- If  $\partial f(x) = \{g\}$ , then f is differentiable at x and  $\nabla f(x) = g$

### Connection to convex geometry

Convex set  $C \subseteq \mathbb{R}^n$ , consider indicator function  $I_C : \mathbb{R}^n \to \mathbb{R}$ ,

$$I_C(x) = I\{x \in C\} = \begin{cases} 0 & \text{if } x \in C \\ \infty & \text{if } x \notin C \end{cases}$$

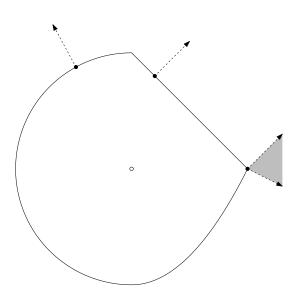

For  $x \in C$ ,  $\partial I_C(x) = \mathcal{N}_C(x)$ , the normal cone of C at x, recall

$$\mathcal{N}_C(x) = \{ g \in \mathbb{R}^n : g^T x \ge g^T y \text{ for any } y \in C \}$$

Why? By definition of subgradient g,

$$I_C(y) \ge I_C(x) + g^T(y - x)$$
 for all  $y$ 

- For  $y \notin C$ ,  $I_C(y) = \infty$
- For  $y \in C$ , this means  $0 \ge g^T(y-x)$

### Subgradient calculus

#### Basic rules for convex functions:

- Scaling:  $\partial(af) = a \cdot \partial f$  provided a > 0
- Addition:  $\partial(f_1 + f_2) = \partial f_1 + \partial f_2$
- Affine composition: if g(x) = f(Ax + b), then

$$\partial g(x) = A^T \partial f(Ax + b)$$

• Finite pointwise maximum: if  $f(x) = \max_{i=1,...m} f_i(x)$ , then

$$\partial f(x) = \operatorname{conv}\left(\bigcup_{i:f_i(x)=f(x)} \partial f_i(x)\right)$$

the convex hull of union of subdifferentials of all active functions at  $\boldsymbol{x}$ 

• General pointwise maximum: if  $f(x) = \max_{s \in S} f_s(x)$ , then

$$\partial f(x) \supseteq \operatorname{cl} \left\{ \operatorname{conv} \left( \bigcup_{s: f_s(x) = f(x)} \partial f_s(x) \right) \right\}$$

and under some regularity conditions (on  $S,f_s$ ), we get an equality above

• Norms: important special case,  $f(x) = ||x||_p$ . Let q be such that 1/p + 1/q = 1, then

$$||x||_p = \max_{||z||_q \le 1} z^T x$$

Hence

$$\partial f(x) = \underset{\|z\|_q \le 1}{\operatorname{argmax}} \ z^T x$$

## Why subgradients?

#### Subgradients are important for two reasons:

- Convex analysis: optimality characterization via subgradients, monotonicity, relationship to duality
- Convex optimization: if you can compute subgradients, then you can minimize (almost) any convex function

### Optimality condition

For any f (convex or not),

$$f(x^*) = \min_{x} f(x) \iff 0 \in \partial f(x^*)$$

I.e.,  $x^*$  is a minimizer if and only if 0 is a subgradient of f at  $x^*$ . This is called the subgradient optimality condition

Why? Easy: g=0 being a subgradient means that for all  $\boldsymbol{y}$ 

$$f(y) \ge f(x^*) + 0^T (y - x^*) = f(x^*)$$

Note the implication for a convex and differentiable function f, with  $\partial f(x) = \{\nabla f(x)\}$ 

#### Derivation of first-order optimality

Example of the power of subgradients: we can use what we have learned so far to derive the first-order optimality condition. Recall that for f convex and differentiable, the problem

$$\min_{x} f(x)$$
 subject to  $x \in C$ 

is solved at x if and only if

$$\nabla f(x)^T (y-x) \ge 0 \quad \text{for all } y \in C$$

Intuitively says that gradient increases as we move away from x. How to see this? First recast problem as

$$\min_{x} f(x) + I_{C}(x)$$

Now apply subgradient optimality:  $0 \in \partial(f(x) + I_C(x))$ 

But

$$0 \in \partial \left( f(x) + I_C(x) \right)$$

$$\iff 0 \in \{ \nabla f(x) \} + \mathcal{N}_C(x)$$

$$\iff -\nabla f(x) \in \mathcal{N}_C(x)$$

$$\iff -\nabla f(x)^T x \ge -\nabla f(x)^T y \text{ for all } \in C$$

$$\iff \nabla f(x)^T (y - x) \ge 0 \text{ for all } y \in C$$

as desired

Note: the condition  $0 \in \partial f(x) + \mathcal{N}_C(x)$  is a fully general condition for optimality in a convex problem. But this is not always easy to work with (KKT conditions, later, are easier)

## Example: lasso optimality conditions

Given  $y \in \mathbb{R}^n$ ,  $X \in \mathbb{R}^{n \times p}$ , lasso problem can be parametrized as:

$$\min_{\beta \in \mathbb{R}^p} \frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\beta\|_1$$

where  $\lambda \geq 0$ . Subgradient optimality:

$$0 \in \partial \left(\frac{1}{2} \|y - X\beta\|_{2}^{2} + \lambda \|\beta\|_{1}\right)$$

$$\iff 0 \in -X^{T}(y - X\beta) + \lambda \partial \|\beta\|_{1}$$

$$\iff X^{T}(y - X\beta) = \lambda v$$

for some  $v \in \partial \|\beta\|_1$ , i.e.,

$$v_i \in \begin{cases} \{1\} & \text{if } \beta_i > 0\\ \{-1\} & \text{if } \beta_i < 0 \ , \quad i = 1, \dots p\\ [-1, 1] & \text{if } \beta_i = 0 \end{cases}$$

Write  $X_1, \dots X_p$  for columns of X. Then subgradient optimality reads:

$$\begin{cases} X_i^T(y - X\beta) = \lambda \cdot \operatorname{sign}(\beta_i) & \text{if } \beta_i \neq 0 \\ |X_i^T(y - X\beta)| \leq \lambda & \text{if } \beta_i = 0 \end{cases}$$

Note: the subgradient optimality conditions do not directly lead to an expression for a lasso solution ... however they do provide a way to check lasso optimality

They are also helpful in understanding the lasso estimator; e.g., if  $|X_i^T(y-X\beta)|<\lambda$ , then  $\beta_i=0$ 

# Example: soft-thresholding

Simplfied lasso problem with X = I:

$$\min_{\beta \in \mathbb{R}^n} \frac{1}{2} \|y - \beta\|_2^2 + \lambda \|\beta\|_1$$

This we can solve directly using subgradient optimality. Solution is  $\beta = S_{\lambda}(y)$ , where  $S_{\lambda}$  is the soft-thresholding operator:

$$[S_{\lambda}(y)]_i = \begin{cases} y_i - \lambda & \text{if } y_i > \lambda \\ 0 & \text{if } -\lambda \leq y_i \leq \lambda \text{ , } i = 1, \dots n \\ y_i + \lambda & \text{if } y_i < -\lambda \end{cases}$$

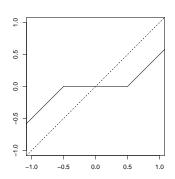

Check: from last slide, subgradient optimality conditions are

$$\begin{cases} y_i - \beta_i = \lambda \cdot \operatorname{sign}(\beta_i) & \text{if } \beta_i \neq 0 \\ |y_i - \beta_i| \leq \lambda & \text{if } \beta_i = 0 \end{cases}$$

Now plug in  $\beta = S_{\lambda}(y)$  and check these are satisfied:

- When  $y_i > \lambda$ ,  $\beta_i = y_i \lambda > 0$ , so  $y_i \beta_i = \lambda = \lambda \cdot 1$
- When  $y_i < -\lambda$ , argument is similar
- When  $|y_i| \leq \lambda$ ,  $\beta_i = 0$ , and  $|y_i \beta_i| = |y_i| \leq \lambda$

Soft-thresholding in one variable:

## Example: distance to a convex set

Recall the distance function to a convex set C:

$$\operatorname{dist}(x,C) = \min_{y \in C} \|y - x\|_2$$

This is a convex function. What are its subgradients?

Write  $dist(x, C) = ||x - P_C(x)||_2$ , where  $P_C(x)$  is the projection of x onto C. Then when dist(x, C) > 0,

$$\partial \operatorname{dist}(x,C) = \left\{ \frac{x - P_C(x)}{\|x - P_C(x)\|_2} \right\}$$

Only has one element, so in fact dist(x, C) is differentiable and this is its gradient

We will only show one direction, i.e., that

$$\frac{x - P_C(x)}{\|x - P_C(x)\|_2} \in \partial \operatorname{dist}(x, C)$$

Write  $u=P_C(x)$ . Then by first-order optimality conditions for a projection,

$$(u-x)^T(y-u) \ge 0$$
 for all  $y \in C$ 

Hence

$$C \subseteq H = \{ y : (u - x)^T (y - u) \ge 0 \}$$

Claim: for any y,

$$dist(y, C) \ge \frac{(x - u)^T (y - u)}{\|x - u\|_2}$$

Check: first, for  $y \in H$ , the right-hand side is  $\leq 0$ 

Now for  $y \notin H$ , we have  $(x-u)^T(y-u) = \|x-u\|_2 \|y-u\|_2 \cos \theta$  where  $\theta$  is the angle between x-u and y-u. Thus

$$\frac{(x-u)^T(y-u)}{\|x-u\|_2} = \|y-u\|_2 \cos \theta = \text{dist}(y,H) \le \text{dist}(y,C)$$

as desired

Using the claim, we have for any y

$$\operatorname{dist}(y,C) \ge \frac{(x-u)^T (y-x+x-u)}{\|x-u\|_2}$$
$$= \|x-u\|_2 + \left(\frac{x-u}{\|x-u\|_2}\right)^T (y-x)$$

Hence  $g = (x - u)/\|x - u\|_2$  is a subgradient of  $\operatorname{dist}(x, C)$  at x
